

Final Report – ABP File No. FRG 19.15

Perennial Forage Variety Evaluation and Demonstration at Multiple Sites in Alberta

Investigators:

Project Lead: Dianne Westerlund, Chinook Applied Research Association (CARA)

Co-Investigators:

Martina Alder (*Vicki Heidt*), Battle River Research Group (BRRG)

Laura Gibney (*Jennifer Duckering*), Foothills Forage and Grazing Association (FFGA)

Sandeep Nain, Gateway Research Association (GRO)

Alyssa Krone, Lakeland Agricultural Research Association (LARA)

Dr. Jacob Marfo, Mackenzie Applied Research Association (MARA)

Nora Paulovich, North Peace Applied Research Association (NPARA)

Dr. Akim Omokanye and Liisa Jeffries, Peace Country Beef and Forage Association (PCBFA)

Dr. Kabal S. Gill, Smokey Applied Research and Demonstration Association (SARDA)

Fito Zamudio, West Central Forage Association (WCFA)

Barry Yaremcio, Beef Nutrition Specialist (Alberta Agriculture and Forestry)

Overview

Project participants wish to thank the Alberta Beef Producers and the Alberta Livestock and Meat Agency for supporting this study.

A selection of perennial forages species and varieties were seeded in 2016 at 8 sites in Alberta to evaluate establishment, yield and nutritional quality. Trial treatments were divided into 3 blocks: Grasses (12 entries), Legumes (15 entries) and Grass/Legume Mixes (9 entries). Data was collected from the sites in 2017 and 2018. Growth was challenged at some sites by adverse conditions both at seeding time and in the 2 years following seeding. Information collected from the sites was grouped by agro-eco regions for reporting. Highest yielding varieties for the Mixed Grassland region over the two years in southern Alberta included Greenleaf pubescent wheatgrass and AC Success hybrid brome; Yellowhead and Rugged alfalfas and mixes AC Success hybrid and Fleet meadow bromes with Yellowhead alfalfa. In the Boreal Transition region of central Alberta, AC Success hybrid brome, Rangelander and Yellowhead alfalfas and the AC Knowles/AC Mountainview sainfoin and the AC Success hybrid brome/Yellowhead alfalfa combinations were the top yielding entries. AC Saltlander green wheatgrass, Greenleaf pubescent wheatgrass and AC Admiral meadow brome were top yielding grasses in the Peace Lowland region. There was no significant difference amongst the legume entries in the Peace trials. Fleet meadow brome/Yellowhead alfalfa was the highest yielding grass/legume mix. Average yields at most sites were much less in 2018 versus 2017, most likely due to a cold, dry spring. Yields of the Fojtan Festulolium, Killarney orchard grass and Courtney tall fescue grasses dropped considerably at most sites between 2017 and 2018, indicating a lack of tolerance to winter and other weather stressors. The AC Mountainview sainfoin and the cicer milk vetch varieties do not appear to persist as well as the majority of the alfalfas.

This study has demonstrated the challenges in evaluating perennial forages in a short period of time. The wide range of growing conditions which occurred during the course of this project (both geographically and year to year) make it difficult to develop sound recommendations on variety

selection for producers. Further evaluation of the establishment, production and longevity of perennial species and varieties is strongly recommended.

Purpose & Objectives:

A. The species/variety trials targeted the following objectives:

1. To provide unbiased, current and comprehensive regional data regarding the establishment, winter survival, yield and economics of specific species and varieties of perennial forage crops.
2. To identify perennial crop species/varieties that demonstrate superior establishment, hardiness, forage yield and nutritional quality characteristics in different eco-regions of Alberta.
3. To assess any benefits from growing mixtures of selected species.

B. The demonstration component will target the following objectives:

1. To demonstrate the regional adaptability of various forage species and varieties.
2. To demonstrate the regional adaptability of various grasses and legumes when planted in mixed stands.

Background

The majority of the annual feed requirement of Alberta's cow herd comes from perennial forages, including both grass and legume. Two thirds of the total cost of maintaining the cow herd is comprised of pasture, stored feed and bedding (Alberta Agriculture's Agriprofits Benchmarks), therefore, managing the supply of perennial forage is very important. Identification of high yielding varieties for different areas of the province will contribute to a positive economic return for Alberta's cattle ranchers.

Forage producers in Alberta have had limited access to information on new perennial crops in recent years. This project is intended to bridge the information gap by evaluating a number of species and varieties at several locations in Alberta. It includes test cultivars which have been developed in recent years but have had limited regional evaluation beside varieties which are commonly grown in the province. Producers will have access to data applicable to regional conditions from the eight test sites in the province.

Study Procedures:

The Perennial Forage Evaluation Trial began with the selection of eight project sites in Alberta. Cereal stubble or chemical fallow sites were chosen for the study at locations near Barrhead, Evansburg, Fort Kent, Fort Vermilion, High Prairie, Manning, Sedalia and Sedgewick (see Table 1). Soil samples were collected at each site in April 2016 and analyzed for basic chemistry and soil nutrients at accredited labs for fertilizer recommendations (Table 2). One demonstration site was established near Cremona.

Sites have been grouped by Alberta Ecoregions (*Alberta Agriculture & Forestry Agriculture Ecoregions in Alberta*) for data compilation purposes:

1. Mixed Grassland (Sedalia)
2. Aspen Parkland (Sedgewick)
3. Boreal Transition (Fort Kent, Barrhead and Evansburg)
4. Peace Lowland (Fort Vermilion, High Prairie and Manning)

Three treatment blocks were included at each site: Pure Stand Grass, Pure Stand Legume and Mixed Grass/Legume. Species and varieties included are listed in Table 3. Four replications of each block were established using a randomized complete block design. Plot sizes ranged from 6.9 to 14.2 m², based on equipment and site availability. Seed was obtained from several companies, including SeCan, Pickseed, Northstar, CPS, Brett Young and Miller Seeds as well as small amounts from Agriculture and Agri-food Canada. Each variety was distributed to all sites from one common source. Two species (Tom Russian wildrye grass and Rangelander alfalfa) were optional so were not seeded at all sites. All grasses and legumes were seeded at 1.5 cm (0.6 inches) depth at rates based on industry accepted rates and those recommended in the Alberta Forage Manual (Table 4). The appropriate fertilizer for the grass and mixed species blocks was applied based on pre-seeding soil test results. The legume plots received a rate of 11-52-0 to meet the recommended phosphorus level. The method of fertilizer application was based on equipment available by participating groups. Legumes were inoculated with powder inoculant except where pre-coated by seed companies. Sainfoin seed was not inoculated. All sites except Fort Kent received a pre-seed burn-off by a glyphosate product. Seed bed preparation at the Fort Kent location was tillage followed by a packer operation. An in-crop herbicide was applied at most sites, along with hand weeding for weed control (Table 3). Reducing competition from weeds during the establishment period is challenging but does have an impact on the resulting forage stand, hence the loss of trials at some locations. A firm seedbed, proper seed placement and appropriate selection and timing of herbicide application can improve the potential of a successful perennial establishment.

Sites were all marked for self-guided tours as well as organized field days.

Similar seeding protocol was utilized for the demonstration site as that used in the replicated trials. Plot size, however, was larger at 2.8 meters by 38 meters (104 m²).

Table 1 Perennial Forage Evaluation Trial Site Summary

	Site	Organization	Trials Completed
Mixed Grassland Brown Soil Zone	Sedalia	CARA	Grasses, Legumes, Mixes
Aspen Parkland Black Soil Zone	Sedgewick	BRRG	Trials were lost to adverse growing conditions (drought, weed and rodent pressure)
Boreal Transition Black and Grey-Wooded Soil Zone	Barrhead	GRO	Grasses, Legumes, Mixes
	Evansburg	WCFA	Grasses, Mixes
	Fort Kent	LARA	Grasses ¹ , Legumes, Mixes ¹
Peace Lowland Black Soil Zone	Fort Vermilion	MARA	Grasses, Legumes, Mixes
	High Prairie	PCBFA/ & SARDA	Grasses, Legumes, Mixes
	Manning	NPARA	Grasses ² , Legumes ² , Mixes ²
Mixed Grassland	Cremona	(FFGA)	Demo of Grasses, Legumes & Mixes

¹ 2018 Yield Data Only

² Data not utilized due to poor establishment and missing plots

Weather Conditions

Precipitation levels at the project sites ranged from below long term average levels to above long term average levels during the course of the project. Total growing season precipitation and average maximum and minimum temperatures are summarized in Tables 5 through 7 (as recorded from the closest ACIS station to each site). All sites except Fort Vermilion received higher levels of precipitation in May of the establishment year (2016) than the long term average for the site. Precipitation during the remainder of the 2016 growing season continued above long term averages except for the Fort Kent and Fort Vermilion sites. The trend for higher moisture levels, however, did not continue into 2017 and 2018 at several sites (Sedgewick, Oyen, Fairview, Manning and Fort Vermilion). The lower rainfall appeared to impact forage yield at all sites.

2016 temperature data indicates a warm trend for all sites early in the spring. The average maximum temperature at Fort Kent was 3 degrees C and High Prairie was 4 degrees C higher than the long term average. Early spring temperatures tended to be lower than the long term average at most sites in 2017 and 2018.

Measurements:

Ease of establishment for the varieties included in the trial was monitored by counting the number of shoots within a 0.25m² area within each plot at 7, 14 and 21 days post seeding in 2016. 21 day post seeding counts appear in Table 8. Observations of plant stands were also made in the spring of 2017 and 2018.

Botanical composition of the grass/legume mixes was determined by hand clipping three 0.25 m² areas per plot at 7.5 cm in height prior to harvest in 2017 and 2018. The grass and legume components were separated, dried to a constant weight and weights were recorded. The proportion of each component within the sample area was calculated.

Height of the varieties (centimeters) was determined by measuring 3 plants in each plot prior to harvest. An assessment of maturity was also made at three points within each plot just prior to harvest. Grass stages were evaluated using morphological stages (1-5) as described by Moore et al (1991) *“Describing and Quantifying Growth Stages of Perennial Forage Grasses*. Legumes were evaluated using morphological stages (stage 0-9) and counted, as described by Kalu and Fick (1981). *“Quantifying Morphological Development of Alfalfa for Studies of Herbage Quality”*. Target harvest stage for yield evaluation was early to mid-bloom for the legumes and at flowering for the grasses. Most of the grasses were at a maturity level of R4 or R5 while the alfalfas were at stages 5 and 6 at harvest.

Yield data from one harvest was collected from the perennial blocks in 2017 and 2018 at 7 sites. Sites which required re-seeding in 2017 were only sampled for yield in 2018. Multiple cuts were not made in either 2017 or 2018 at any of the trial sites. Harvest yield included the full plot growth clipped to a height of 7.5 cm using a forage harvester. The entire plot sample was weighed and a sub-sample of approximately 500 g from each was collected and air dried to a constant weight (at temperatures not greater than 50° C) before the final weight was recorded.

Combined sub-samples from reps 1 and 2 as well as from reps 3 and 4 were submitted to A & L Labs for analysis of basic nutrients, including Crude Protein, Acid Detergent Fibre, Neutral Detergent Fibre, Total Digestible Nutrients, and Total Energy (Lactation, Gain and Maintenance). Wet chemistry was used for the analysis of Calcium, Copper, Phosphorus, Potassium, Sulphur, Magnesium, Zinc, Iron, Manganese and Sodium minerals.

A partial economic analysis including establishment, seed and chemical costs and the economic return of each variety is summarized in Tables 22 through 30. Costs included within the analysis were limited to materials and seed. Other expenses such as the labor and equipment employed in establishing, maintaining and harvesting the varieties are assumed to be the same for all treatments so were not included in the analysis. Returns were calculated using the 2018 AFSC regional forage survey values and dry matter yields.

Results and Discussion – Establishment

Plant counts 21 days post seeding in 2016 indicated establishment at the sites ranged from poor to excellent (Table 7). The importance of adequate moisture and reducing weed competition were demonstrated at 4 sites where re-seeding was necessary: Fort Kent (grass and mix blocks), Fort Vermilion (all blocks), Manning (all blocks) and Sedgewick (all blocks). Poor initial establishment was attributed to low moisture, flooding, equipment failure and/or weed pressure. Excellent moisture conditions supported growth of all varieties at the Sedalia site in Special Area 3 where plant counts exceeded what is considered excellent establishment in some varieties.

Fortunately, the growth within most treatments improved so that by harvest in 2017 the stand in the majority of plots was acceptable, with the exception of the Sedgewick site which was challenged with weed and rodent pressures and so was removed from the project. Manning data was not reported due to variability within each block caused by poor establishment and/or weed competition. The legume block at Evansburg was also abandoned due to weed competition. In general, observations from this trial indicate plant counts soon after seeding are not always a reliable indication of future production. An acceptable stand may just take additional time for establishment.

Table 8a Plant Counts – 2016 (average per 1/4 m²) at 21 Days Post Seeding

Grasses	Barrhead	Fort Kent	Sedge	Sedalia	Fort Verm	Manning	Fairview	WCFA

¹ Average % Fleet from each year of harvest

AC Success hybrid brome was the tallest of the grass varieties seeded at the Sedalia site, followed by Greenleaf pubescent wheatgrass. Greenleaf was the best yielding in each of 2017 and 2018. Other varieties showing good potential include AC Saltlander green wheatgrass, AC Knowles hybrid brome and Fleet meadow brome. Shortest and lowest yielding at this site in 2017 was Fojtan festolium and growth was too short to harvest on 2018. Average yield from the entire block in 2018 was less than half of the 2017 yield most likely due to cold growing conditions in the spring and lower precipitation levels.

¹ Average % Fleet Meadow Brome and AC Yellowhead from each year of harvest

Average yield from the mix of grass and alfalfa treatments was comparable to the straight legumes but greater than the straight grasses. The cold spring and low precipitation again influenced production as 2018 yields were 50% less as compared to 2017. All three combinations including Yellowhead alfalfa were amongst the top yielding in the trial. Success hybrid brome and Spredor 5 alfalfa yielded slightly less. The percent composition of the legume in the various combinations tended to drop from 2017 to 2018. This was particularly evident in the brome/sainfoin combinations.

¹Barrhead and Evansburg Sites

²Fort Kent, Barrhead and Evansburg Sites

³Average from all sites in both years of the study

The grass treatment block at the Fort Kent site was reseeded so was not harvested in 2017. AC Success hybrid brome grass was the tallest of the grass varieties included in the trial at 9% taller than the check Fleet brome grass and also produced the most dry matter yield in both years of the trial. Shortest specie was the Fojtan festolium, which yielded a bit higher than the lowest yielding entry of Kirk crested wheat grass.

¹ High Prairie Site² Average from all sites in both years of the study

Tallest legume variety, tested only at the High Prairie site, was the Rangelander alfalfa in the Peace Lowland trials. 44-44 and Spredor 5 were next tallest overall. There were no significant differences between yields of the legume entries in either 2017 or 2018. Average yields were within a few percent of the check Yellowhead for all except the Rugged and Rangelander alfalfas. Average yields in the trial were approximately 600 pounds less in 2018 than 2017.

¹ Fort Vermilion and High Prairie Sites² Fleet Meadow Brome + Yellowhead Alfalfa ³Average from all sites in both years of the study

As reported in the other trial sites, the grasses are taller than the legumes in the combinations in the Peace Lowland mix evaluations. The percentage of legumes within the mixes tended to increase between 2017 and 2018. Overall average yields were over 900 lb/A less in 2018 than in 2017. The Yellowhead alfalfa and brome mixes were amongst the highest yielding combinations, although the AC Knowles hybrid brome/AC Mountainview sainfoin yielded highest in 2018.

Results and Discussion – Nutritional Components (as contributed by Barry Yaremcio, M. Sc., P. Ag., Beef and Forage Specialist, Alberta Agriculture and Forestry)

Forage quality can be affected by many factors:

- 1) Annual rainfall and snow cover (especially early spring moisture conditions)
- 2) Soil type (black, brown, luvisol, etc.)
- 3) Soil fertility at time of seeding and subsequent fertilizer application
- 4) Yield and maturity of the crop
- 5) Age of stand / plant density (plants per square foot)
- 6) Plant species present and percentages of each
- 7) Wind and temperature
- 8) Weeds or invasive species present
- 9) Available sunlight (smoke impact in 2018)
- 10) Diseases, insects, and pests
- 11) Hail or frost
- 12) Harvest and storage management

Average values of nutrients contained in forages often are 40 to 75% below what is required by the animal type that is being fed. Thus, testing available feeds is the only way to develop a balanced feeding program.

Comparing nutrient content of grasses, legumes and grass mixes is challenging, but trends can be commented on. It goes without testing that cobalt and iodine are virtually absent from all forages grown in western Canada. Selenium is also very deficient; but there are small localized areas in the province where concentrations are high and problems have been encountered. The Crow's Nest Pass is one such area.

Fibre deposition occurs throughout the growing season. As fibre levels increase, the energy density in the plant decreases. After heading, it is not uncommon for grass plants to have the protein content drop by 1 to 1.5% per week and energy levels to be 3 to 4 points of TDN lower as well. (*Suleiman et. al., J Range Management 52: 75 – 82 Jan 1999*).

The results from this trial confirm that quality is variable and that the factors mentioned above have impact on the final quality of the forage, thus reinforcing the need to submit samples for analysis to establish quality. If trace mineral analysis has not been done in the past, it is worth completing a test for trace minerals to determine the baseline. Trace mineral levels do not change much from year to year. It might require that a custom mineral be developed for certain operations.

Based on the variability observed both within and between trial sites and year of harvest within this study, as well as the influence of location specificities and timing of harvest, it was determined there was no value in calculating regional averages. Nutritional values for the treatments within each

individual site are reported in the Appendix. Comments by Barry Yaremcio on the specific nutritional components are documented there.

Results and Discussion – Partial Economic Analysis

The following tables provide a partial economic analysis for the average yield of varieties during the first two years of production in each region. The entire cost of establishing the forage is taken from the revenue generated in those first two years, not amortized over the lifespan of the forage stand. As would be expected, higher yielding varieties tended to provide the highest net return. A large jump in hay prices occurred between 2017 and 2018 due to a shortage of hay throughout the province. This increase in value had a large impact on the net returns for each entry in the study. The net return of the trials in the Peace Lowland tended to be less than in the central and southern regions where the hay values are typically higher.

Results and Discussion – Demonstration Site Summary

Single strips of 11 grasses, 14 legumes and 9 mixes were seeded on June 7, 2016 at a site near Cremona. Moisture conditions were dry at the time of seeding. Volunteer barley grew abundantly across the demo strips and was removed by cutting and baling August 19. 19.1 inches of rainfall was received at the site between May 23 and September 11, 2016, with the majority falling from mid-July on. Individual strips within the site were marked for self-guided tours.

A good snow cover was received during the winter of 2016/2017, providing good soil moisture for the spring. 150 cows grazing swaths in the adjacent field had access to the demo for 7 days in January.

The site again received a thick layer of snow cover during the 2017/2018 winter. 145 cows grazed swaths in the adjacent field as well as the site for one week in January. The snow resulted in good spring moisture, however below average rainfall for that area (approximately 5 inches) was received during the summer.

Growth looked good throughout the site. All alfalfa and cicer milk vetch varieties were more prominent than the sainfoin. The site was not clipped or harvested in anyway during the growing season throughout the three-year project, with only light off-season grazing by cows in January.

Knowledge Transfer Activities

All project participants carried out a number of activities sharing information related to the study and production of perennial forages in general (see summary below).

An overview of the project was presented to a provincial audience at the:

- Alberta Forage Industry Network (AFIN) Annual General Meeting, March 7, 2017 in Leduc
- Agricultural Research and Extension Council of Alberta (ARECA) Annual General Meeting, March 8, 2017 in Leduc
- Alberta Beef Forage and Grazing Center Annual General Meeting February 7, 2018 in Leduc
- ARECA association staff toured the Sedalia site during Summer Training August 9 2016
- Beef Industry Conference booth by ARECA Forage and Livestock Team members; August 2017

Individual groups also provided updates for their local membership in annual report publications, newsletters and meetings. Updates and photos were also provided in newsletters, Instagram, facebook, and twitter accounts.

A provincial focused Fact Sheet is currently under construction which will be shared amongst all groups and posted on association websites for exposure to a wide audience.

Future Recommendations

Gathering yield data over a longer term will provide more meaningful information for Alberta's forage producers. Forage stands are rarely left in rotation/production for just 2 years due to the investment required for establishment. Different seeding rates should perhaps be considered for different regions of the province.

Nutritional Components – Individual Sites (as contributed by Barry Yaremcio, M. Sc., P. Ag., Beef and Forage Specialist, Alberta Agriculture and Forestry)

After reviewing the data, there are differences in forage quality between years and also between the entries within each site. Comments will be made by individual sites. If no comment is made about an individual nutrient, they are considered to be within normal ranges found in Alberta. The comparisons are based on data summarized from feed test results obtained from the Soil and Animal Nutrition Lab that was located at the O. S. Longman Building and compiled from 1976 to 1986 (AgDex 100/81-6). Nutrient values comparisons are “% of normal” compared to averages.

Comparing nutrients concentrations found in forages (Table 1) to animal requirements (Table 2) are summarized in the tables below. Discussion will be limited to mature cows. Nutrient requirements for other classes of animals vary.

Table 48 Average Nutrient Concentrations Found in Alberta Forages

	Grass Forages	Legume Forages	Mixed Grass / Legume Hay
All nutrients listed on a dry matter basis			
Protein (%)	10.3	18.5	12.5
Calcium (%)	0.4	1.6	1.0
Acid Detergent Fibre (%)	38.0	33.0	36.0
Phosphorus (%)	0.15	0.21	0.18
Magnesium (%)	0.15	0.3	0.22
Potassium (%)	1.15	1.75	1.5
Sodium (%)	0.03	0.04	0.02
Sulfur (%)	0.15	0.20	0.16
Copper (mg/kg)	4.5	5.5	6.5
Manganese (mg/kg)	65.0	35.0	45.0
Zinc (mg/kg)	25.0	22.0	24.0

Table 49 Animal Requirements

	Cows Mid Pregnancy	Cows Late Pregnancy	Cows Post Calving
1400 pound animal			
All nutrients listed on a dry matter basis			
Protein (%)	7.0	9.0	11.0
Digestible Energy (mcal)	30.8	35.0	47.0
Calcium (%)	0.4	0.4	0.5
Phosphorus (%)	0.2	0.2	0.25
Magnesium (%)	0.2	0.2	0.25
Potassium (%)	0.7	0.7	0.8
Sodium (%)	0.09	0.09	0.09
Sulfur (%)	0.15	0.15	0.15
Copper (mg/kg)	12.0	12.0	12.0
Manganese (mg/kg)	47.0	47.0	47.0
Zinc (mg/kg)	35.0	35.0	35.0

When using the tables from the forage associations, the calculation to obtain the actual value of a nutrient is (actual value + (actual value x percentage)). For example: if the manganese is 75% above average for a grass hay: $(65 + (65 \times 75/100)) = 114.75$.

2017 (average of 2 samples)	2018 (average of 2 samples)	No color	Average of 2017 & 2018						

2017 Grasses:

- Protein values are 50 to 75% below average
- Cutting date was slightly late (1 week) based on reported Acid Detergent Fibre values
- Some samples have Neutral Detergent Fibre values > 60%. May reduce voluntary feed intakes
- Calcium values are 10% to 50% below average

- Phosphorus values are 25% below to 20% over the average
- Sulfur values are average to 35% below average
- Magnesium values are 30% below average to 25% above average
- Copper values are 20% to 35% below average
- Manganese values are 25 to 80% below average
- Zinc values are 35 to 50% below average

2018 Grasses:

- Protein values are 25 to 50% below average
- Cutting date was slightly late (1 to 3 weeks) based on reported Acid Detergent Fibre values
- Some samples have Neutral Detergent Fibre values > 60%. May reduce voluntary feed intakes
- Calcium values are average to 50% below average
- Phosphorus values are 10% to 35% below average
- Magnesium values are 30% below to 60% above average
- Sulfur values are average to 50% below average
- Copper values are 35% below to 25% above average
- Manganese values are 25 to 90% below average
- Zinc values are 10 to 50% below average

2017 (average of 2 samples) 2018 (average of 2 samples) No color Average of 2017 & 2018

2017 Grasses:

- Protein values are 20% below to 20% above average
- Cutting date was slightly late (1 week) based on reported Acid Detergent Fibre values
- Some samples have Neutral Detergent Fibre values > 60%. Can reduce voluntary feed intakes
- Calcium values are average to 35% below average
- Phosphorus values are 30% below to 25% above average
- Magnesium values are 35% below to 25% above average
- Sulfur values are 30% below to 30% above average
- Copper values are 35% below to 15% above average
- Manganese values are 30% to 60% below average

- Zinc values are 10% below to 140% above average

2018 Grasses:

- Protein values are 20% below to 20% above average
- Cutting date was slightly late (1 week) based on reported Acid Detergent Fibre values
- Some samples have Neutral Detergent Fibre values > 60%. Can reduce voluntary feed intakes
- Calcium values are average to 35% below average
- Phosphorus values are 30% below to 25% above average
- Magnesium values are 35% below to 25% above average
- Sulfur values are 35% below to 30% above average
- Copper values are 35% below to 15% above average
- Manganese values are 30% to 60% below average
- Zinc values are 10% below to 140% above average

2017 (average of 2 samples)

2018 (average of 2 samples)

¹ Average of 2017 & 2018**2017 Grasses:**

- Protein values are 15% to 70% above average
- Cutting date was slightly late (1 - 2 weeks) based on reported Acid Detergent Fibre values
- Some samples have Neutral Detergent Fibre values > 60%. Can reduce voluntary feed intakes
- Calcium values are 20% to 60% above average
- Phosphorus values are 10% below to 250% above average
- Magnesium values are 30% below to 30% above average
- Sulfur values are 100 to 125% above average
- Copper values are average to 35% below average
- Manganese values are 40% to 65% below average
- Zinc values are 50% below to 20% above average

2018 Grasses:

- Protein values are 60% below to 20% above average
- Cutting date was slightly late (2 - 3 weeks) based on reported Acid Detergent Fibre values
- Almost all samples have Neutral Detergent Fibre values > 60%. Can reduce voluntary feed intakes
- Calcium values are 35% below to 300% above average
- Phosphorus values are 40% below to 80% above average
- Magnesium values are 35% below to 300% above average
- Sulfur values are 10% below to 50% above average
- Copper values are average to 85% below average
- Manganese values are 15% below to 215% above average
- Zinc values are 70% below to 15% above average

2017 (average of 2 samples)		2018 (average of 2 samples)				¹ Average of 2017 & 2018		

2017 Legumes:

- Protein values are 20% below to 20% above average
- Cutting date was at the correct time based on reported Acid Detergent Fibre values
- Neutral Detergent Fibre levels are average
- Calcium values are average to 250% above average
- Phosphorus values are average to 55% above average
- Magnesium values are 15% below to 100% above average
- Sulfur values are 100% to 125% above average
- Copper values are average to 40% below average
- Manganese values are 50% to 65% below average
- Zinc values are 50% below to 20% above average

2018 Legumes:

- Protein values are 20% to 55% below average
- Cutting date was 2 – 3 weeks late based on reported Acid Detergent Fibre values
- Some samples had Neutral Detergent Fibre levels > 60%. Can reduce voluntary intake
- Calcium values are 30% below to 50% above average
- Phosphorus values are 50% below to 10% above average
- Magnesium values are 45% below to 80% above average
- Sulfur values are 50% below to 25% above average
- Copper values are 75% below to 10% above average
- Manganese values are 35% below to 200% above average
- Zinc values are 75% below to 50% above average
